## MATLAB Function Reference

## fminsearch

Find minimum of unconstrained multivariable function using derivative-free method

## Syntax

```
x = fminsearch(fun,x0)
x = fminsearch(fun,x0,options)
[x,fval] = fminsearch(...)
[x,fval,exitflag] = fminsearch(...)
[x,fval,exitflag,output] = fminsearch(...)
```

## Description

fminsearchfinds the minimum of a scalar function of several variables, starting at an initial estimate. This is generally referred to asunconstrained nonlinear optimizatian
$\mathrm{x}=\mathrm{fminsearch}(f u n, x 0)$ starts at the pointx0 and finds a local minimumx of the function described in fun. $x 0$ can be a scalar, vector, or matrix. fun is a function handle. See Function Handlesin the MATLAB Programming documentation for more information.

Parameterizing Functions Called by Function Functioris the MATLAB Mathematics documentation, explains how to pass additional parameters to your objective functioflun. See also Example 2 and Example 3 below. $x=$ fminsearch (fun, $x 0$, optionsminimizes with the optimization parameters specified in the structureoptions You can define these parameters using theoptimsetfunction. fminsearchuses these optionsstructure fields:

| Display | Level of display.' off' displays no output;'iter' displays output at each iteration;' final' displays just the final output; 'notify' (default) displays output only if the function does not converge. |
| :---: | :---: |
| FunValCheck | Check whether objective function values are valid! on' displays an error when the objective function returns a value that is complex, Inf or NaN. 'off' (the default) displays no error. |
| MaxFunEvals | Maximum number of function evaluations allowed |
| MaxIter | Maximum number of iterations allowed |
| OutputFen | User-defined function that is called at each iteration. Se@utput Functionin the Optimization Toolbox for more information. |
| PlotFcns | User-defined plot function that is called at each iteration. Seelot Functionsin the Optimization Toolbox for more information. |
| TolFun | Termination tolerance on the function value |
| TolX | Termination tolerance onx |

[x,fval] = fminsearch(...returns infval the value of the objective functionfun at the solutionx.

```
[x,fval,exitflag] = fminsearch(...\etaeturns a valueexitflagthat describes the exit
condition offminsearch
```

1 fminsearchconverged to a solutionx.
$0 \quad$ Maximum number of function evaluations or
iterations was reached.
-1
Algorithm was terminated by the output function.
[x,fval,exitflag,output] = fminsearch(.. seturns a structureoutput that contains information about the optimization:

```
output.algorithm Algorithm used
output.funcCount Number of function evaluations
output.iterationsNumber of iterations
output.message Exit message
```

## Arguments

fun is the function to be minimized. It accepts an inpu* and returns a scalar $f$, the objective function evaluated atx. The functionfun can be specified as a function handle for an M -file function

```
x = fminsearch(@myfun, x0)
```

where myfun is an M-file function such as

```
function f = myfun(x)
f = .. % Compute function value at x
```

or as a function handle for ananonymous functionsuch as

```
x = fminsearch(@(x)sin(x^2), x0);
```

Other arguments are described in the syntax descriptions above.

## Examples

## Example 1

A classic test example for multidimensional minimization is the Rosenbrock banana functior

$$
f(x)=100\left(x_{2}-x_{1}^{2}\right)^{2}+\left(1-x_{1}\right)^{2}
$$

The minimum is at ( 1,1 ) and has the value 0 . The traditional starting point is $(-1.2,1)$. The anonymous function shown here defines the function and returns a function handle called banana:

```
banana = @(x) 100*(x(2)-x(1)^2)^2+(1-x(1))^2;
```

Pass the function handle tofminsearch

```
[x,fval] = fminsearch(banana,[-1.2, 1])
```

This produces

```
x =
    1.0000 1.0000
fval =
8.1777e-010
```

This indicates that the minimizer was found to at least four decimal places with a value near zero.

## Example 2

If fun is parameterized, you can use anonymous functions to capture the problem-dependent parameters. For example, suppose you want to minimize the objective functionmyfundefined by the following M-file function.

```
function f = myfun(x,a)
f = x(1)^2 + a*x(2)^2;
```

Note that myfun has an extra parameter a, so you cannot pass it directly tofminsearch To optimize for a specific value ofa, such as a $=1.5$.

1. Assign the value toa.
```
a = 1.5; % define parameter first
```

2. Call fminsearchwith a one-argument anonymous function that captures that value of a and calls myfun with two arguments:
```
x = fminsearch(@(x) myfun(x,a), [0,1])
```

## Example 3

You can modify the first example by adding a parametera to the second term of the banana function:

$$
f(x)=100\left(x_{2}-x_{1}^{2}\right)^{2}+\left(a-x_{1}\right)^{2}
$$

This changes the location of the minimum to the pointa, $\left.a^{\wedge} 2\right]$. To minimize this function for a specific value of a, for example $a=\operatorname{sqrt}(2)$, create a one-argument anonymous function that captures the value of.

```
a = sqrt(2);
banana = @(x)100*(x(2)-x(1)^2)^2+(a-x(1) )^2;
```

Then the statement

```
[x,fval] = fminsearch(banana, [-1.2, 1], ...
    optimset('TolX',1e-8));
```

seeks the minimum [sqrt (2), 2]to an accuracy higher than the default orx.

## Algorithm

fminsearch uses the simplex search method o[1]. This is a direct search method that does not use numerical or analytic gradients.

If $n$ is the length of $x$, a simplex in $n$-dimensional space is characterized by then +1 distinct vectors that are its vertices. In two-space, a simplex is a triangle; in three-space, it is a pyramid. At each step of the search, a new point in or near the current simplex is generated. The function value at the new point is compared with the function's values at the vertices of the simplex and, usually, one of the vertices is replaced by the new point, giving a new simplex. This step is repeated until the diameter of the simplex is less than the specified tolerance.

## Limitations

fminsearchcan often handle discontinuity, particularly if it does not occur near the solution fminsearch may only give local solutions.
fminsearchonly minimizes over the real numbers, that is $\boldsymbol{x}$ must only consist of real numbers and $f(x)$ must only return real numbers. Wher $x$ has complex variables, they must be split into real and imaginary parts.
